

# Duplicate Insert and Text Output

The below API demonstrates two update queries. As update queries do not return any meaningful information, below API uses `Text` tag to send back the feedback submitted.

## Feedback POST request with Text Tag

```
<?xml version="1.0" encoding="UTF-8" ?>
<Resource xmlns="http://xml.metamug.net/resource/1.0" v="1.0">
  <Request method="POST">
    <Param name="source" type="text" value="feedback"/>
    <Sql id="addFeedback" type="update">
      INSERT into feedback (name,email,issue,description) VALUES
      ($name,$email,$issue,$description)
    </Sql>
    <Sql id="addUser" type="update">
      INSERT IGNORE INTO feedback_user(emailUsers,registration_source) VALUES ($email,$source)
    </Sql>
    <Text id="feedback">
      name: $name,feedback: $issue - $description
    </Text>
  </Request>
</Resource>
```

## Inserting Duplicate Records

`addUser` ignores duplicate inserts preventing the POST API from failing in case the user already exists in the table.
